A uniformly convergent difference scheme on a modified Shishkin mesh for the singularly perturbed reaction-diffusion boundary value problem

Enes Duvnjaković, Samir Karasuljić, Vedad Pasic, Helena Zarin

Abstract

We are considering a semilinear singular perturbation reaction – diffusion boundary value problem which contains a small perturbation parameter that acts on the highest order derivative. We construct a difference scheme on an arbitrary nonequidistant mesh using a collocation method and Green’s function. We show that the constructed difference scheme has a unique solution and that the scheme is stable. The central result of the paper is $\epsilon$-uniform convergence of almost second order for the discrete approximate solution on a modified Shishkin mesh. We finally provide two numerical examples which illustrate the theoretical results on the uniform accuracy of the discrete problem, as well as the robustness of the method.

Keywords: semilinear reaction–diffusion problem, singular perturbation, boundary layer, Shishkin mesh, layer-adapted mesh, $\epsilon$-uniform convergence.

2010 MSC: 65L10, 65L60.

1. Introduction

We consider the semilinear singularly perturbed problem

$$\epsilon^2 y''(x) = f(x, y) \quad \text{on} \quad [0, 1],$$

$$y(0) = 0, \quad y(1) = 0,$$

$\epsilon > 0$.
where $0 < \epsilon < 1$. We assume that the nonlinear function $f$ is continuously differentiable, i.e. that $f \in C^k ([0, 1] \times \mathbb{R})$, for $k \geq 2$ and that $f$ has a strictly positive derivative with respect to $y$

$$\frac{\partial f}{\partial y} = f_y \geq m > 0 \text{ on } [0, 1] \times \mathbb{R} \quad (m = \text{const}). \quad (3)$$

The solution $y$ of the problem (1)–(3) exhibits sharp boundary layers at the endpoints of $[0, 1]$ of $O(\epsilon \ln 1/\epsilon)$ width. It is well known that the standard discretization methods for solving (1)–(3) are unstable and do not give accurate results when the perturbation parameter $\epsilon$ is smaller than some critical value, see e.g. pages 16–17 of [6] and pages 46–47 of [22] for more details. With this in mind, we therefore need to develop a method which produces a numerical solution for the starting problem with a satisfactory value of the error. Moreover, we additionally require that the error does not depend on $\epsilon$; in this case we say that the method is uniformly convergent with respect to $\epsilon$ or $\epsilon$-uniformly convergent.

More precisely, we are looking for robust methods in the sense of the following definition:

**Definition 1.1.** [15] Let $y$ be the solution of a singularly perturbed problem, and let $\overline{y}$ be a numerical approximation of $y$ obtained by a numerical method with $N$ degrees of freedom. The numerical method is said to be uniformly convergent or robust with respect to the perturbation parameter $\epsilon$ in the norm $\|\cdot\|$ if

$$\|y - \overline{y}\| \leq \kappa(N) \text{ for } N \geq N_0$$

with a function $\kappa$ satisfying

$$\lim_{N \to +\infty} \kappa(N) = 0 \text{ and } \partial_\epsilon \kappa \equiv 0,$$

and with some threshold value $N_0 > 0$ that is independent of $\epsilon$.

From definition 1.1 it is evidently clear that the numerical solutions $\overline{y}$ of given continuous problems obtained by using a $\epsilon$-uniformly convergent method satisfy the condition

$$\|y - \overline{y}\| \leq C\kappa(N), \quad \kappa(N) \to 0, \quad N \to +\infty,$$

where $y$ is the exact solution of the original continuous problem, $\|\cdot\|$ is the discrete maximum norm, $N$ is the number of mesh points that is independent of $\epsilon$ and $C > 0$ is a constant which does not depend of $N$ or $\epsilon$, see [6, 15] for more information. We therefore demand that the numerical solution $\overline{y}$ converges to $y$ for every value of the perturbation parameter in the domain $0 < \epsilon < 1$ with respect to the discrete maximum norm $\|\cdot\|$. The problem (1)–(2) has been researched by many authors with various assumptions on $f(x, y)$. Various different difference schemes have been constructed which are uniformly convergent on equidistant meshes as well as schemes on specially constructed, mostly Shishkin and Bakhvalov-type meshes, where $\epsilon$-uniform convergence of second order has been demonstrated, see e.g. [11, 13, 14, 24, 26, 28, 29], as well as schemes with $\epsilon$-uniform convergence of order greater than two, see e.g. [7, 8, 9, 32, 33]. These difference schemes were usually constructed using the finite difference method and its modifications or collocation methods with polynomial splines. Nonlinear problems of more general or different type than the problem (1)–(2) were studied in e.g. [5, 12, 17, 30, 31]. A large number of difference schemes belongs to the group of exponentially fitted schemes or their uniformly convergent versions. Such schemes were mostly used in numerical solving of corresponding linear singularly perturbed boundary value problems on equidistant meshes, see e.g. [4, 10, 19, 21, 27]. They were less frequently used for numerical solving of nonlinear singularly perturbed boundary value problems, see e.g. [18, 25].
Our present work represents a synthesis of these two approaches, i.e. we want to construct a difference scheme which belongs to the group of exponentially fitted schemes and apply this scheme to a corresponding nonequidistant layer-adapted mesh. The main motivation for constructing such a scheme is obtaining an $\epsilon$-uniform convergent method, which will be guaranteed by the layer-adapted mesh, and then further improving the numerical results by using an exponentially fitted scheme.

This method was first presented by Boglaev [2], where the discretisation of the problem (1)–(3) on a modified Bakhvalov mesh was analysed and first order uniform convergence with respect to $\epsilon$ was demonstrated. Afterwards, Boglaev [3] also analysed the analogous 2D problem. We therefore aim to construct an $\epsilon$-uniformly convergent difference scheme on a modified Shishkin mesh, using the results presented in [2].

This paper has the following structure. Section 1. provides background information and introduces the main concepts used throughout. In Section 2, we construct our difference scheme based on which we generate the system of equations whose solving gives us the numerical solution values at the mesh points. We also prove the existence and uniqueness theorem for the numerical solution. In Section 3, we construct the mesh, where we use a modified Shishkin mesh with a smooth enough generating function in order to discretize the initial problem. In Section 4, we show $\epsilon$-uniform convergence and its rate. In Section 5, we provide some numerical experiments and discuss our results and possible future research.

**Notation.** Throughout this paper we denote by $C$ (sometimes subscripted) a generic positive constant that may take different values in different formulae, always independent of $N$ and $\epsilon$. We also (realistically) assume that $\epsilon \leq \frac{\ell}{4}$. Throughout the paper, we denote by $\| \cdot \|$ the usual discrete maximum norm $\|u\| = \max_{0 \leq i \leq N} |u_i|$, $u \in \mathbb{R}^{N+1}$, as well as the corresponding matrix norm.

### 2. Scheme construction

Consider the differential equation (1) in an equivalent form

$$L_{\epsilon} y(x) := \epsilon^2 y''(x) - \gamma y(x) = \psi(x, y(x)) \quad \text{on} \quad [0, 1],$$

where

$$\psi(x, y) = f(x, y) - \gamma y,$$

and $\gamma \geq m$ is a chosen constant. In order to obtain a difference scheme needed to calculate the numerical solution of the boundary value problem (1)–(2), using an arbitrary mesh $0 = x_0 < x_1 < x_2 < \ldots < x_N = 1$ we construct a solution of the following boundary value problem

$$L_{\epsilon} y_i(x) = \psi(x, y_i(x)) \quad \text{on} \quad (x_i, x_{i+1}),$$

$$y_i(x_i) = y(x_i), \quad y_i(x_{i+1}) = y(x_{i+1}),$$

for $i = 0, 1, \ldots, N - 1$. It is clear that $y_i(x) \equiv y(x)$ on $[x_i, x_{i+1}], \ i = 0, 1, \ldots, N - 1$. The solutions of corresponding homogeneous boundary value problems

$$L_{\epsilon} u_i^I(x) := 0 \quad \text{on} \quad (x_i, x_{i+1}),$$

$$u_i^I(x_i) = 1, \quad u_i^I(x_{i+1}) = 0,$$

$$L_{\epsilon} u_i^{II}(x) := 0 \quad \text{on} \quad (x_i, x_{i+1}),$$

$$u_i^{II}(x_i) = 0, \quad u_i^{II}(x_{i+1}) = 1,$$

for $i = 0, 1, \ldots, N - 1$, are known, see [21], i.e.

$$u_i^I(x) = \frac{\sinh (\beta (x_{i+1} - x))}{\sinh (\beta h_i)} \quad \text{and} \quad u_i^{II}(x) = \frac{\sinh (\beta (x - x_i))}{\sinh (\beta h_i)},$$
for $i = 0, 1, \ldots, N - 1$, where $x \in [x_i, x_{i+1}]$, $\beta = \frac{\sqrt{7}}{\epsilon}$, $h_i = x_{i+1} - x_i$. The solution of (5)–(6) is given by
\[
y_i(x) = C_1 u_i^1(x) + C_2 u_i^H(x) + \int_{x_i}^{x_{i+1}} G_i(x, s) \psi(s, y(s)) ds, \quad x \in [x_i, x_{i+1}],
\]
where $G_i(x, s)$ is the Green's function associated with the operator $L_\epsilon$ on the interval $[x_i, x_{i+1}]$. The function $G_i(x, s)$ in this case has the following form
\[
G_i(x, s) = \frac{1}{\epsilon^2 w_i(s)} \begin{cases} u_i^H(x)u_i^1(s), & x_i \leq x \leq s \leq x_{i+1}, \\ u_i^1(x)u_i^H(s), & x_i \leq s \leq x \leq x_{i+1}, \end{cases}
\]
where $w_i(s) = u_i^H(s) (u_i^1)'(s) - u_i^1(s) (u_i^H)'(s)$. Clearly $w_i(s) \neq 0$, $s \in [x_i, x_{i+1}]$. It follows from the boundary conditions (6) that $C_1 = y(x_i) =: y$, $C_2 = y(x_{i+1}) =: y_{i+1}$, $i = 0, 1, \ldots, N - 1$. Hence, the solution $y_i(x)$ of (5)–(6) on $[x_i, x_{i+1}]$ has the following form
\[
y_i(x) = y_i u_i^1(x) + y_{i+1} u_i^H(x) + \int_{x_i}^{x_{i+1}} G_i(x, s) \psi(s, y(s)) ds.
\]
(7)
The boundary value problem
\[
L_\epsilon y(x) := \psi(x, y) \quad \text{on} \quad (0, 1), \quad y(0) = y(1) = 0,
\]
has a unique continuously differentiable solution $y \in C^{k+2}(0, 1)$. Since $y_i(x) \equiv y(x)$ on $[x_i, x_{i+1}]$, $i = 0, 1, \ldots, N - 1$, we have that $y_i'(x_i) = y_{i-1}'(x_i)$, for $i = 1, 2, \ldots, N - 1$. Using this in differentiating (7), we get that
\[
y_{i-1}'(u_{i-1}')(x_i) + y_i \left[ (u_{i-1}')'(x_i) - (u_i')'(x_i) \right] + y_{i+1} \left[ - (u_i')'(x_i) \right]
= \frac{\partial}{\partial x} \left[ \int_{x_i}^{x_{i+1}} G_i(x, s) \psi(s, y(s)) ds - \int_{x_{i-1}}^{x_i} G_{i-1}(x, s) \psi(s, y(s)) ds \right]_{x=x_i}.
\]
(8)
Since we have that
\[
(u_{i-1}')(x_i) = \frac{-\beta}{\sinh(\beta h_{i-1})}, \quad (u_i')'(x_i) = \frac{\beta}{\sinh(\beta h_i)},
\]
\[
(u_{i-1}')'(x_i) - (u_i')'(x_i) = \frac{\beta}{\tanh(\beta h_{i-1}) + \beta \tanh(\beta h_i)},
\]
equation (8) becomes
\[
\frac{\beta}{\sinh(\beta h_{i-1})} y_{i-1} - \left( \frac{\beta}{\tanh(\beta h_{i-1}) + \beta \tanh(\beta h_i)} \right) y_i + \frac{\beta}{\sinh(\beta h_i)} y_{i+1}
= \frac{1}{\epsilon^2} \left[ \int_{x_{i-1}}^{x_i} u_{i-1}'(s) \psi(s, y(s)) ds + \int_{x_i}^{x_{i+1}} u_i'(s) \psi(s, y(s)) ds \right],
\]
(9)
for $i = 1, 2, \ldots, N - 1$ and $y_0 = y_N = 0$. We cannot in general explicitly compute the integrals on the RHS of (9). In order to get a simple enough difference scheme, we approximate the function $\psi$ on $[x_{i-1}, x_i] \cup [x_i, x_{i+1}]$ using $\overline{\psi}_i = \frac{1}{4} \left[ \psi(x_{i-1}, \overline{y}_{i-1}) + 2 \psi(x_i, \overline{y}_i) + \psi(x_{i+1}, \overline{y}_{i+1}) \right]$, where $\overline{y}_i$ are
approximate values of the solution $y$ of the problem (1)–(2) at points $x_i$. We get that

\[
\frac{\beta}{\sinh(\beta h_{i-1})} \bar{y}_{i-1} - \left( \frac{\beta}{\tanh(\beta h_{i-1})} + \frac{\beta}{\tanh(\beta h_i)} \right) \bar{y}_i + \frac{\beta}{\sinh(\beta h_i)} \bar{y}_{i+1} = \frac{1}{\epsilon^2} \psi(x_{i-1}, \bar{y}_{i-1}) + 2\psi(x_i, \bar{y}_i) + \psi(x_{i+1}, \bar{y}_{i+1}) \left[ \int_{x_i}^{x_{i+1}} u_{i-1}''(s) ds + \int_{x_i}^{x_{i+1}} u_i'(s) ds \right],
\]

for $i = 1, 2, \ldots, N - 1$ and $\bar{y}_0 = \bar{y}_N = 0$. Using equation (4), we get that

\[
(3a_i + d_i + \Delta d_{i+1}) (\bar{y}_{i-1} - \bar{y}_i) - (3a_{i+1} + d_{i+1} + \Delta d_i) (\bar{y}_i - \bar{y}_{i+1}) - f(x_{i-1}, \bar{y}_{i-1}) + f(x_{i+1}, \bar{y}_{i+1}) (\Delta d_i + \Delta d_{i+1}) = 0,
\]

for $i = 1, 2, \ldots, N - 1$ and $\bar{y}_0 = \bar{y}_N = 0$, where

\[
a_i = \frac{1}{\sinh(\beta h_{i-1})}, \quad d_i = \frac{1}{\tanh(\beta h_{i-1})}, \quad \Delta d_i = d_i - a_i.
\]

Using the scheme (10) we form a corresponding discrete analogue of (1)–(3)

\[
F_0 \bar{y} := \bar{y}_0 = 0,
\]

\[
F_i \bar{y} := \frac{\gamma}{\Delta d_i + \Delta d_{i+1}} \left[ (3a_i + d_i + \Delta d_{i+1}) (\bar{y}_{i-1} - \bar{y}_i) - (3a_{i+1} + d_{i+1} + \Delta d_i) (\bar{y}_i - \bar{y}_{i+1}) - f(x_{i-1}, \bar{y}_{i-1}) + f(x_{i+1}, \bar{y}_{i+1}) (\Delta d_i + \Delta d_{i+1}) \right] = 0,
\]

\[
F_N \bar{y} := \bar{y}_N = 0,
\]

where $i = 1, 2, \ldots, N - 1$. The solution $\bar{y} := (\bar{y}_0, \bar{y}_1, \ldots, \bar{y}_N)^T$ of the problem (12)–(14), i.e. $F \bar{y} = 0$, where $F = (F_0, F_1, \ldots, F_N)^T$ is an approximate solution of the problem (1)–(3).

**Theorem 2.1.** The discrete problem (12)–(14) has a unique solution $\bar{y}$ for $\gamma \geq f_y$. Also, for every $u, v \in \mathbb{R}^{N+1}$ we have the following stabilizing inequality

\[
\|u - v\| \leq \frac{1}{m} \| Fu - Fv \|.
\]

**Proof.** We use a technique from [9] and [32], while the proof of existence of the solution of $F \bar{y} = 0$ is based on the proof of the relation: $\| (F')^{-1} \| \leq C$, where $F'$ is the Fréchet derivative of $F$. The Fréchet derivative $H := F'(\bar{y})$ is a tridiagonal matrix. Let $H = [h_{ij}]$. The non-zero elements of this tridiagonal matrix are

\[
h_{0,0} = h_{N,N} = 1,
\]

\[
h_{i,i} = \frac{2\gamma}{\Delta d_i + \Delta d_{i+1}} \left[ (a_i + a_{i+1}) - 2(d_i + d_{i+1}) - \frac{1}{\gamma} \frac{\partial f}{\partial y} (x_i, \bar{y}_i) (\Delta d_i + \Delta d_{i+1}) \right] < 0,
\]

\[
h_{i,i-1} = \frac{\gamma}{\Delta d_i + \Delta d_{i+1}} \left[ (\Delta d_i + \Delta d_{i+1}) \left( 1 - \frac{1}{\gamma} \frac{\partial f}{\partial y} (x_{i-1}, \bar{y}_{i-1}) \right) + 4a_i \right] > 0,
\]

\[
h_{i,i+1} = \frac{\gamma}{\Delta d_i + \Delta d_{i+1}} \left[ (\Delta d_{i+1} + \Delta d_i) \left( 1 - \frac{1}{\gamma} \frac{\partial f}{\partial y} (x_{i+1}, \bar{y}_{i+1}) \right) + 4a_{i+1} \right] > 0,
\]
where \( i = 1, \ldots, N - 1 \). Hence \( H \) is an \( L \)-matrix. Moreover, \( H \) is an \( M \)-matrix since \( |h_{i,i}| - |h_{i,i-1}| - |h_{i-1,i}| \geq 4m \). Consequently
\[
\|H^{-1}\| \leq \frac{1}{m}.
\] (15)

Using Hadamard’s theorem (see e.g. Theorem 5.3.10 from [20]), we get that \( F \) is an homeomorphism. Since clearly \( \mathbb{R}^{N+1} \) is non-empty and 0 is the only image of the mapping \( F \), we have that (12)–(14) has a unique solution.

The proof of second part of the Theorem 2.1 is based on a part of the proof of Theorem 3 from [7]. We have that
\[
Fu - Fv = (F'w)(u - v)
\]
for some \( w = (w_0, w_1, \ldots, w_N)^T \in \mathbb{R}^{N+1} \). Therefore
\[
u - v = (F'w)^{-1}(Fu - Fv)\]
and finally due to inequality (15) we have that
\[
\|u - v\| = \|(F'w)^{-1}(Fu - Fv)\| \leq \frac{1}{m} \|Fu - Fv\|.
\]

\[\Box\]

3. Mesh construction

Since the solution of the problem (1)–(3) changes rapidly near \( x = 0 \) and \( x = 1 \), the mesh has to be refined there. Various meshes have been proposed by various authors. The most frequently analyzed are the exponentially graded meshes of Bakhvalov, see [1], and piecewise uniform meshes of Shishkin, see [23].

Here we use the smoothed Shishkin mesh from [16] and we construct it as follows. Let \( N + 1 \) be the number of mesh points and \( q \in (0, 1/2) \) and \( \sigma > 0 \) are mesh parameters. We define the Shishkin mesh transition point by
\[
\lambda := \min \left\{ \frac{\sigma \epsilon}{\sqrt{m}} \ln N, q \right\}
\]
and we choose \( \sigma = 2 \).

Remark 3.1. For the sake of simplicity in representation, we assume that \( \lambda = 2\epsilon(\sqrt{m})^{-1}\ln N \), as otherwise the problem can be analyzed in the classical way. We shall also assume that \( qN \) is an integer. This is easily achieved by choosing \( q = 1/4 \) and \( N \) divisible by 4 for example.

The mesh \( \Delta : x_0 < x_1 < \cdots < x_N \) is generated by \( x_i = \varphi(i/N) \) with the mesh generating function
\[
\varphi(t) := \begin{cases} \frac{\lambda}{q} t & t \in [0, q], \\ p(t-q)^3 + \frac{\lambda}{q} t & t \in [q, 1/2], \\ 1 - \varphi(1-t) & t \in [1/2, 1], \end{cases}
\]
where \( p \) is chosen such that \( \varphi(1/2) = 1/2 \), i.e. \( p = \frac{1}{2}(1 - \frac{\lambda}{q})(\frac{1}{2} - q)^{-3} \). Note that \( \varphi \in C^1[0,1] \) with \( \|\varphi\|_\infty, \|\varphi''\|_\infty \leq C \). Therefore we have that the mesh sizes \( h_i = x_{i+1} - x_i, \ i = 0, 1, \ldots, N - 1 \) satisfy
\[
h_i = \int_{t_i}^{t_{i+1}} \varphi'(t)dt \leq CN^{-1},
\]
\[
|h_{i+1} - h_i| = \left| \int_{t_i}^{t_{i+1}} \int_t^{t_{i+1}} \varphi''(s)ds \right| \leq CN^{-2}.
\]

(17)  (18)
4. Uniform convergence

In this section we prove the theorem on $\epsilon$-uniform convergence of the discrete problem (12)–(14). The proof uses the decomposition of the solution $y$ to the problem (1)–(2) to the layer $s$ and a regular component $r$ given by

**Theorem 4.1.** [29] The solution $y$ to problem (1)–(2) can be represented as

$$y = r + s,$$

where for $j = 0, 1, \ldots, k + 2$ and $x \in [0, 1]$ we have that

$$|x^{(j)}(x)| \leq C,$$  \hspace{1cm}  \text{(19)}

$$|s^{(j)}(x)| \leq C\epsilon^{-j} \left(e^{-\frac{x}{\sqrt{m}}} + e^{-\frac{1-x}{\sqrt{m}}} \right).$$  \hspace{1cm}  \text{(20)}$$

**Remark 4.2.** Note that $e^{-\frac{x}{\sqrt{m}}} \geq e^{-\frac{1-x}{\sqrt{m}}}$ for $x \in [0, 1/2]$ and $e^{-\frac{x}{\sqrt{m}}} \leq e^{-\frac{1-x}{\sqrt{m}}}$ for $x \in [1/2, 1]$. These inequalities and the estimate (20) imply that the analysis of the error value can be done on the part of the mesh which corresponds to $x \in [0, 1/2]$ omitting the function $e^{-\frac{x}{\sqrt{m}}}$, keeping in mind that on this part of the mesh we have that $h_{i-1} \leq h_i$. An analogous analysis would hold for the part of the mesh which corresponds to $x \in [1/2, 1]$ but with the omision of the function $e^{-\frac{x}{\sqrt{m}}}$ and using the inequality $h_{i-1} \geq h_i$.

From here on in we use $\epsilon^2 y''(x_k) = f(x_k, y(x_k))$, $k \in \{i - 1, i, i + 1\}$, and

$$y_{i-1} - y_i = -y_i h_{i-1} + \frac{y''^2}{2} h_{i-1}^2 - \frac{y''^2}{6} h_{i-1}^3 + \frac{y^{(iv)}(\xi^-)}{24} h_{i-1}^4,$$  \hspace{1cm}  \text{(21)}

$$y_i - y_{i+1} = -y_i h_i + \frac{y''^2}{2} h_i^2 - \frac{y''^2}{6} h_i^3 - \frac{y^{(iv)}(\xi^+)}{24} h_i^4,$$  \hspace{1cm}  \text{(22)}

$$y''_{i-1} = y''_i - y''_{i-1} + \frac{y^{(iv)}(\xi^-)}{2} h_{i-1}^2,$$  \hspace{1cm}  \text{(23)}

$$y''_{i+1} = y''_i + y''_{i+1} + \frac{y^{(iv)}(\xi^+)}{2} h_i^2,$$  \hspace{1cm}  \text{(24)}

where $\xi^- \in (x_{i-1}, x_i)$, $\xi^+ \in (x_i, x_{i+1})$. We begin with a lemma that will be used further on in the proof on the uniform convergence.

**Lemma 4.3.** On the part of the modified Shishkin mesh (16) where $x_i, x_{i+1} \in \left[\left[x_{N/4-1}, \lambda\right] \cup [\lambda, 1/2]\right]$, assuming that $\epsilon \leq C/N$, for $i = N/4, \ldots, N/2 - 1$ we have the following estimate

$$\left(\frac{\cosh(\beta h_{i-1}) - 1}{\gamma \sinh(\beta h_{i-1})} + \frac{\cosh(\beta h_i) - 1}{\gamma \sinh(\beta h_i)}\right)^{-1} \left|\frac{y_{i-1} - y_i - y_i - y_{i+1}}{\sinh(\beta h_{i-1}) - \sinh(\beta h_i)}\right| \leq C/N^2.$$  \hspace{1cm}  \text{(25)}$$

**Proof.** We are using the decomposition from Theorem 4.1 and expansions (23), (24). For the
For the layer component $r$ we have that

$$
\left( \frac{\cosh(\beta h_{i-1}) - 1}{\gamma \sinh(\beta h_{i-1})} + \frac{\cosh(\beta h_i) - 1}{\gamma \sinh(\beta h_i)} \right)^{-1} \left| \frac{r_{i-1} - r_i}{\sinh(\beta h_{i-1})} - \frac{r_i - r_{i+1}}{\sinh(\beta h_i)} \right| \leq \gamma \left| \beta h_{i-1} h_i \sum_{n=1}^{+\infty} \frac{\beta^{2n}(h_i^{2n} - h_{i-1}^{2n})}{(2n+1)!} \right| \sum_{n=1}^{+\infty} \frac{(\beta h_i)^{2n}}{(2n)!} \sinh(\beta h_{i-1})
$$

$$
+ \gamma \left| \frac{r''(\mu^+_i)}{2} \sum_{n=0}^{+\infty} \frac{(\beta h_{i-1})^{2n+1} h_i^2}{(2n+1)!} \right| + \gamma \left| \frac{r''(\mu^-_i)}{2} \sum_{n=0}^{+\infty} \frac{(\beta h_i)^{2n+1}}{(2n+1)!} h_{i-1}^2 \right|.
$$

(26)

First we want to estimate the expressions containing only the first derivatives in the RHS of inequality (26). From the identity $a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + \ldots + ab^{n-2} + b^{n-1})$, $n \in \mathbb{N}$, and the inequalities $h_{i-1} \leq h_i$, $i = 1, \ldots, N, i = 1, \ldots, \frac{N}{2} - 1$, we get that $h_i^n - h_{i-1}^n \leq n(h_i - h_{i-1})h_i^{n-1}$, which yields that

$$
\frac{\beta^{2n}(h_i^{2n} - h_{i-1}^{2n})}{(2n+1)!} \leq \frac{\beta^{2n}(h_i^2 - h_{i-1}^2)h_i^{2(n-1)}}{(2n)!}, \forall n \in \mathbb{N}.
$$

(27)

Using inequality (27) together with (19), we get that

$$
\gamma \left| \beta h_{i-1} h_i \sum_{n=1}^{+\infty} \frac{\beta^{2n}(h_i^{2n} - h_{i-1}^{2n})}{(2n+1)!} \right| \leq C(h_i - h_{i-1}).
$$

(28)

Now we want to estimate the terms containing the second derivatives from the RHS of (26). Using inequality (19) we get that

$$
\left| \frac{r''(\mu^+_i)}{2} \sum_{n=0}^{+\infty} \frac{(\beta h_{i-1})^{2n+1} h_i^2}{(2n+1)!} \right| \leq \left| \frac{r''(\mu^+_i) h_i^2}{\beta^2 h_i^2} \right| \leq C \epsilon^2,
$$

(29)

$$
\left| \frac{r''(\mu^-_i)}{2} \sum_{n=0}^{+\infty} \frac{(\beta h_i)^{2n+1}}{(2n+1)!} h_{i-1}^2 \right| \leq C(\epsilon^2 + h_{i-1} h_i).
$$

(30)

For the layer component $s$, first we have that

$$
\left( \frac{\cosh(\beta h_{i-1}) - 1}{\gamma \sinh(\beta h_{i-1})} + \frac{\cosh(\beta h_i) - 1}{\gamma \sinh(\beta h_i)} \right)^{-1} \left| \frac{s_{i-1} - s_i}{\sinh(\beta h_{i-1})} - \frac{s_i - s_{i+1}}{\sinh(\beta h_i)} \right| \leq \gamma \left| \beta h_i (s_{i-1} - s_i) - \beta h_{i-1} (s_i - s_{i+1}) \right| \sum_{n=1}^{+\infty} \frac{(\beta h_{i-1})^{2n}}{(2n)!} \sinh(\beta h_{i-1})
$$

$$
+ \gamma \left| \beta h_i (s_{i-1} - s_i) - \beta h_{i-1} (s_i - s_{i+1}) \right| \sum_{n=1}^{+\infty} \frac{(\beta h_i)^{2n}}{(2n)!} \sinh(\beta h_{i-1})
$$

$$
\leq \gamma \left| \frac{\beta h_i(s_{i-1} - s_i) - \beta h_{i-1}(s_i - s_{i+1})}{\sum_{n=1}^{+\infty} (\beta h_{i-1})^{2n}} \sinh(\beta h_{i-1}) \right| + \gamma \left| \frac{\beta h_i(s_{i-1} - s_i) - \beta h_{i-1}(s_i - s_{i+1})}{\sum_{n=1}^{+\infty} (\beta h_i)^{2n}} \sinh(\beta h_{i-1}) \right|.
$$

(31)
We look at the terms on the RHS of (31) separately. The first term of the RHS of (31) can be bounded by
\[
\gamma \left| \frac{\beta h_i s_{i-1} - s_i - \beta h_{i-1} (s_i - s_{i+1})}{\sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n)! \sinh(\beta h_{i-1})} \right| \leq \frac{\beta h_i}{\sinh(\beta h_{i-1})} \leq \frac{C}{N^2},
\]
which we also obtain for the third term of the RHS of (31), i.e.
\[
\gamma \sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n+1)! |s_i - s_{i+1}| \leq \frac{C}{N^2}.
\]

The second term RHS of (31) contains the ratio \(\frac{\beta h_i}{\sinh(\beta h_{i-1})}\). Although this ratio is bounded by \(\frac{h_i}{h_{i-1}}\), this quotient is not bounded for \(x_i = \lambda\) when \(\epsilon \to 0\). This is why we are going to estimate this expression separately on the transition part and on the nonequidistant part of the mesh. In the case \(i = N,\) using the fact that \(\sum_{n=1}^{+\infty} \frac{x^{2n}}{(2n)!} = \cosh x - 1,\) \(\sum_{n=1}^{+\infty} \frac{x^{2n+1}}{(2n+1)!} = \sinh x - x,\ \forall x \in \mathbb{R},\) and the fact that the function \(r(x) = \frac{\sinh x - x}{\cosh x - 1}\) takes values from the interval \((0, 1)\) when \(x > 0,\) we have that the second term RHS of (31) can be bounded by
\[
\gamma \left| \frac{\beta h_i \sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n+1)! (s_{i-1} - s_i)}{\sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n)! \sinh(\beta h_{i-1})} \right| \leq \gamma \frac{|s_{i-1} - s_i|}{\sinh(\beta h_{i-1})} \leq \frac{C}{N^2}.
\]

In the case when \(i = N + 1, \ldots, N - \frac{T}{2} - 1,\) we can use \(\frac{\sum_{n=1}^{+\infty} \frac{x^{2n}}{(2n)!}}{\sum_{n=1}^{+\infty} \frac{x^{2n+1}}{(2n+1)!}} = \frac{\sinh x - x}{x(\cosh x - 1)} = p(x)\) and \(0 < p(x) < \frac{1}{3}\) for \(x > 0\) and therefore the second term from the RHS of (31) can be bounded by
\[
\gamma \left| \frac{\beta h_i \sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n+1)! (s_{i-1} - s_i)}{\sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n)! \sinh(\beta h_{i-1})} \right| \leq \gamma \frac{\beta h_i}{\beta h_{i-1}} \frac{\sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n+1)!}{\sum_{n=1}^{+\infty} (\beta h_i)^{2n} (2n)!} |s_{i-1} - s_i| \leq \frac{C}{N^2}.
\]

Using equations (17), (18), (26) and (28)–(35), we complete the proof of the lemma.
Now we state the main theorem on $\epsilon-$uniform convergence of our difference scheme and specially chosen layer-adapted mesh.

**Theorem 4.4.** The discrete problem (12)–(14) on the mesh from Section 2. is uniformly convergent with respect to $\epsilon$ and

$$\max_i |y_i - \bar{y}_i| \leq C \left\{ \begin{array}{ll}
\frac{\ln^2 N}{N^2}, & i = 0, \ldots, \frac{N}{4} - 1 \\
\frac{1}{N^2}, & i = \frac{N}{4}, \ldots, \frac{3N}{4} \\
\frac{\ln^2 N}{N^2}, & i = \frac{3N}{4} + 1, \ldots, N,
\end{array} \right.$$  

where $y$ is the solution of the problem (1), $\bar{y}$ is the corresponding numerical solution of (12)–(14) and $C > 0$ is a constant independent of $N$ and $\epsilon$.

**Proof.** We shall use the technique from [32], i.e. since we have stability from Theorem 2.1, we have that $\|y - \bar{y}\| \leq C \|Fy - F\bar{y}\|$ and since (12)–(14) implies that $F\bar{y} = 0$, it only remains to estimate $\|Fy\|$.

Let $i = 0, 1, \ldots, \frac{N}{4} - 1$. The discrete problem (12)–(14) can be written down on this part of the mesh in the following form

$$F_0y = 0,$$

$$F_iy = \frac{\gamma}{\Delta d_i + \Delta d_{i+1}} \left[ (3a_i + d_i + \Delta d_{i+1}) (y_{i-1} - y_i) - (3a_{i+1} + d_{i+1} + \Delta d_i) (y_i - y_{i+1}) - f(x_{i-1}, y_{i-1}) + 2f(x_i, y_i) + f(x_{i+1}, y_{i+1}) (\Delta d_i + \Delta d_{i+1}) \right]$$

$$= \frac{\gamma}{2\Delta d_i} \left[ (3a_i + d_i + \Delta d_i) (y_{i-1} - y_i) - (y_i - y_{i+1})) - 2f(x_{i-1}, y_{i-1}) + 2f(x_i, y_i) + f(x_{i+1}, y_{i+1}) \Delta d_i \right]$$

$$= \frac{\gamma}{2(\cosh(\beta h_i) - 1)} \left[ (2 + 2 \cosh(\beta h_i)) (y_{i-1} - y_i) - (y_i - y_{i+1})) - 2f(x_{i-1}, y_{i-1}) + 2f(x_i, y_i) + f(x_{i+1}, y_{i+1}) (\cosh(\beta h_i) - 1) \right],$$

for $i = 1, 2, \ldots, \frac{N}{4} - 1$. Using the expansions (21) and (22), we get that

$$F_iy = \frac{\gamma}{\beta^2 h_i^2 + 2\mathcal{O} (\beta^4 h_i^4)} \left[ (4 + \beta^2 h_i^2 + 2\mathcal{O} (\beta^4 h_i^4)) \left( y'' y_i h_i^2 + \frac{y^{(iv)} (\xi_{i-1}) + y^{(iv)} (\xi_i^+)}{24} h_i^4 \right) \right]$$

$$= \frac{1}{\beta^2} \left( 4y'' + \frac{y^{(iv)} (\xi_{i-1}) + y^{(iv)} (\xi_i^+)}{2} \right) \left( \beta^2 h_i^2 + 2\mathcal{O} (\beta^4 h_i^4) \right)$$

for $i = 1, 2, \ldots, \frac{N}{4} - 1$. The proof is complete.
\[ E_N = \max_{0 \leq i < N} \left| y(x_i) - \bar{y}^N(x_i) \right|, \]  

(36)

where \( \bar{y}^N(x_i) \) is the value of the numerical solutions at the mesh point \( x_i \), where the mesh has \( N \) subintervals, and \( y(x_i) \) is the value of the exact solution at \( x_i \). The rate of convergence \( \text{Ord} \) is calculated using

\[ \text{Ord} = \frac{\ln E_N - \ln E_{2N}}{\ln \frac{2N}{k+1}}, \]

where \( N = 2^k, k = 6, 7, \ldots, 13 \). Tables 1 and 2 give the numerical results for our two examples and we can see that the theoretical and experimental results match.
Example 5.1. Consider the following problem, see [9]

$$\epsilon^2 y'' = y + \cos^2(\pi x) + 2(\epsilon \pi)^2 \cos(2\pi x) \quad \text{for } x \in (0, 1), \quad y(0) = y(1) = 0.$$ 

The exact solution of this problem is given by $y(x) = \frac{e^{-\epsilon} + e^{-\frac{1}{1-x^2}} - \cos^2(\pi x)}{1 + e^{-\frac{1}{1-x^2}}}$. The nonlinear system was solved using the initial condition $y_0 = -0.5$ and the value of the constant $\gamma = 1$.

Table 1: Error $E_N$ and convergence rates Ord for approximate solution for example 5.1
Example 5.2. Consider the following problem

$$\epsilon^2 y'' = (y - 1)(1 + (y - 1)^2) + g(x) \quad \text{for } x \in (0, 1), \quad y(0) = (1) = 0,$$

where $g(x) = \frac{\cosh^3 \frac{1-2x}{2\epsilon}}{\cosh \frac{1}{2\epsilon}}$. The exact solution of this problem is given by $y(x) = 1 - \frac{e^{-\frac{x}{\epsilon}} + e^{-\frac{1-x}{\epsilon}}}{1 + e^{-\frac{1}{\epsilon}}}$. The nonlinear system was solved using the initial guess $y_0 = 1$. The exact solution implies that $0 \leq y \leq 1$, $\forall x \in [0, 1]$, so the value of the constant $\gamma = 4$ was chosen in such a way as to have that $\gamma \geq f_g(x, y), \forall (x, y) \in [0, 1] \times [0, 1] \subset [0, 1] \times \mathbb{R}$.

![Numerical solution graphs from example 5.2 for values $\epsilon = 2^{-3}, 2^{-5}, 2^{-7}$](image-url)
In the analysis of examples 5.1 and 5.2 and the corresponding result tables, we can observe the robustness of the constructed difference scheme, even for small values of the perturbation parameter $\epsilon$. Note that the results presented in tables 1 and 2 already suggest $\epsilon$-uniform convergence of second order.

The presented method can be used in order to construct schemes of convergence order greater than two. In constructing such schemes, the corresponding analysis should not be more difficult that the analysis for our constructed difference scheme. In the case of constructing schemes for solving a two-dimensional singularly perturbed boundary value problem, if one does not take care that functions of two variables do not appear during the scheme construction, the analysis should not be substantially more difficult then for our constructed scheme. In such a case it would be enough to separate the expressions with the same variables and the analysis is reduced to the previously done one-dimensional analysis.
